We sequenced the 29,751-base genome of the severe acute respiratory syndrome (SARS)-associated coronavirus known as the Tor2 isolate. The genome sequence reveals that this coronavirus is only moderately related to other known coronaviruses, including two human coronaviruses, HCoV-OC43 and HCoV-229E. Phylogenetic analysis of the predicted viral proteins indicates that the virus does not closely resemble any of the three previously known groups of coronaviruses. The genome sequence will aid in the diagnosis of SARS virus infection in humans and potential animal hosts (using polymerase chain reaction and immunological tests), in the development of antivirals (including neutralizing antibodies), and in the identification of putative epitopes for vaccine development.

An outbreak of atypical pneumonia, referred to as severe acute respiratory syndrome (SARS) and first identified in Guangdong Province, China, has spread to several countries. The severity of this disease is such that the mortality rate appears to be ~3 to 6%

be as high as 43 to 55% in people older than 60 years (1). A number of laboratories worldwide have undertaken the identification of the causative agent (2, 3). The National Microbiology Laboratory in Canada obtained the Tor2 isolate from a patient in Toronto and succeeded in

## CLINICAL TRIALS

# Fraud and Ethics Charges Hit Stroke Drug Trial

AMSTERDAM, THE NETHERLANDS—It should have been a landmark study in stroke research, capable of changing the way the disease is treated. But the Second European Stroke Prevention Study (ESPS 2), a major clinical trial of a drug to prevent repeat strokes—involving almost 7000 patients in 13 European countries—has become mired in controversy. A paper describing promising results from the trial, published earlier this month in the *Journal of the Neurological Sciences*, was first turned down by *The Lancet* in part because of ethical concerns over the use of placebos. And it has been further tainted by

ing the 2 years the patients were followed; aspirin, which was also tested, gave a risk reduction of 18%; but combined the two lessened the chances of a stroke by 37%, with relatively few side effects. The death rates in all three treatment groups were about the same, however, and did not differ significantly from that of the placebo group.

But the encouraging news in the ESPS 2 results was soured by the paper's guarded suggestions of data problems discovered during the study. The paper refers to "serious inconsistencies in patient case record forms and compliance assay determinations" at one

Boehringer Ingelheim. "We subsequently had some conversations and carried out an investigation, but we were unable to establish either guilt or innocence. So we left it at that," says Sissingh.

Chris Verhorst, medical director of Boehringer Ingelheim Netherlands, says the trial's organizers first became concerned about the large number of patients enrolled by a single physician and the unusual dedication with which they took their daily medication. Suspicions grew, says Lowenthal, when blood pressure data submitted by the physician turned out to be distributed along a perfect Gaussian curve—which is highly unlikely in a patient sample of this size.

According to the trial protocol, patient compliance was tested by assaying drug levels in plasma from 15% of the patients. Lowenthal says analysis of the suspect samples showed that all of them came from just two individuals, and all contained both drugs, which would have

### ECOTOXICOLOGY

# Environmentally relevant concentrations of microplastic particles influence larval fish ecology

Oona M. Lönnstedt\* and Peter Eklöv

The widespread occurrence and accumulation of plastic waste in the environment have become a growing global concern over the past decade. Although some marine organisms have been shown to ingest plastic, few studies have investigated the ecological effects of plastic waste on animals. Here we show that exposure to environmentally relevant concentrations of microplastic polystyrene particles (90 micrometers) inhibits hatching, decreases growth rates, and alters feeding preferences and innate behaviors of European perch (*Perca fluviatilis*) larvae. Furthermore, individuals exposed to microplastics do not respond to olfactory threat cues, which greatly increases predator-induced mortality rates. Our results demonstrate that microplastic particles operate both chemically and physically on larval fish performance and development.

## Editorial Retraction

**Jeremy Berg**

Editor-in-Chief

After an investigation, the Central Ethical Review Board in Sweden has recommended the retraction of the Report “Environmentally relevant concentrations of microplastic particles influence larval fish ecology,” by Oona M. Lönnstedt and Peter Eklöv, published in *Science* on 3 June 2016 (1). *Science* ran an Editorial Expression of Concern regarding the Report on 1 December 2016 (2). The Review Board’s report, dated 21 April 2017, cited the following reasons for their recommendation: (i) lack of ethical approval for the experiments; (ii) absence of original data for the experiments reported in the paper; (iii) widespread lack of clarity concerning how the experiments were conducted. Although the authors have told *Science* that they disagree with elements of the Board’s report, and although Uppsala University has not yet concluded its own investigation, the weight of evidence is that the paper should now be retracted. In light of the Board’s recommendation and a 28 April 2017 request from the authors to retract the paper, *Science* is retracting the paper in full.

The partial pressure of CO<sub>2</sub> in the oceans has increased rapidly over the past century, driving ocean acidification and raising concern for the stability of marine ecosystems<sup>1–3</sup>. Coral reef fishes are predicted to be especially susceptible to end-of-century ocean acidification on the basis of several high-profile papers<sup>4,5</sup> that have reported profound behavioural and sensory impairments—for example, complete attraction to the chemical cues of predators under conditions of ocean acidification. Here, we comprehensively and transparently show that—in contrast to previous studies—end-of-century ocean acidification levels have negligible effects on important behaviours of coral reef fishes, such as the avoidance of chemical cues from predators, fish activity levels and behavioural lateralization (left–right turning preference). Using data simulations, we additionally show that the large effect sizes and small within-group variances that have been reported in several previous studies are highly improbable. Together, our findings indicate that the reported effects of ocean acidification on the behaviour of coral reef fishes are not reproducible, suggesting that behavioural perturbations will not be a major consequence for coral reef fishes in high CO<sub>2</sub> oceans.

## REEF ECOLOGY

# Chemically mediated behavior of recruiting corals and fishes: A tipping point that may limit reef recovery

Danielle L Dixon,<sup>1</sup> David Abrego,<sup>2</sup> Mark E Hay<sup>1\*</sup>

Coral reefs are in global decline, converting from dominance by coral to dominance by seaweed. Once seaweeds become abundant, coral recovery is suppressed unless herbivores return to remove seaweeds, and corals then recruit. Variance in the recovery of fishes and corals is not well understood. We show that juveniles of both corals and fishes are repelled by chemical cues from fished, seaweed-dominated reefs but attracted to cues from coral-dominated areas where fishing is prohibited. Chemical cues of specific seaweeds from degraded reefs repulsed recruits, and cues from specific corals that are typical of healthy reefs attracted recruits. Juveniles were present at but behaviorally avoided recruiting to degraded reefs dominated by seaweeds. For recovery, degraded reefs may need to be managed to produce cues that attract, rather than repel, recruiting corals and fishes.

**C**orals are foundation species, creating the biogenic matrix on which reef structure, function, and biodiversity depend (1, 2). However, corals are in decline. Coral cover has declined by 80% in the Caribbean and

processes preventing juvenile recruitment (10–12). Some seaweeds chemically reduce the recruitment and survival of corals for centimeters around seaweed perimeters (15), possibly selecting for coral larvae that use chemical cues to reject

swell, and presumably other physical conditions (fig. S1). Our non-MPA reefs have higher seaweed and lower coral cover than many nonprotected reefs, but some unprotected reefs in the Caribbean (5), Red Sea (17), and Indian Ocean (18) are similar in seaweed and coral cover, and numerous reefs are trending toward the conditions on our non-MPA reefs (3, 4). Thus, the contrasts of juvenile fish and coral behavior toward the divergent reef states we investigated may be informative about some present and numerous future reefs.

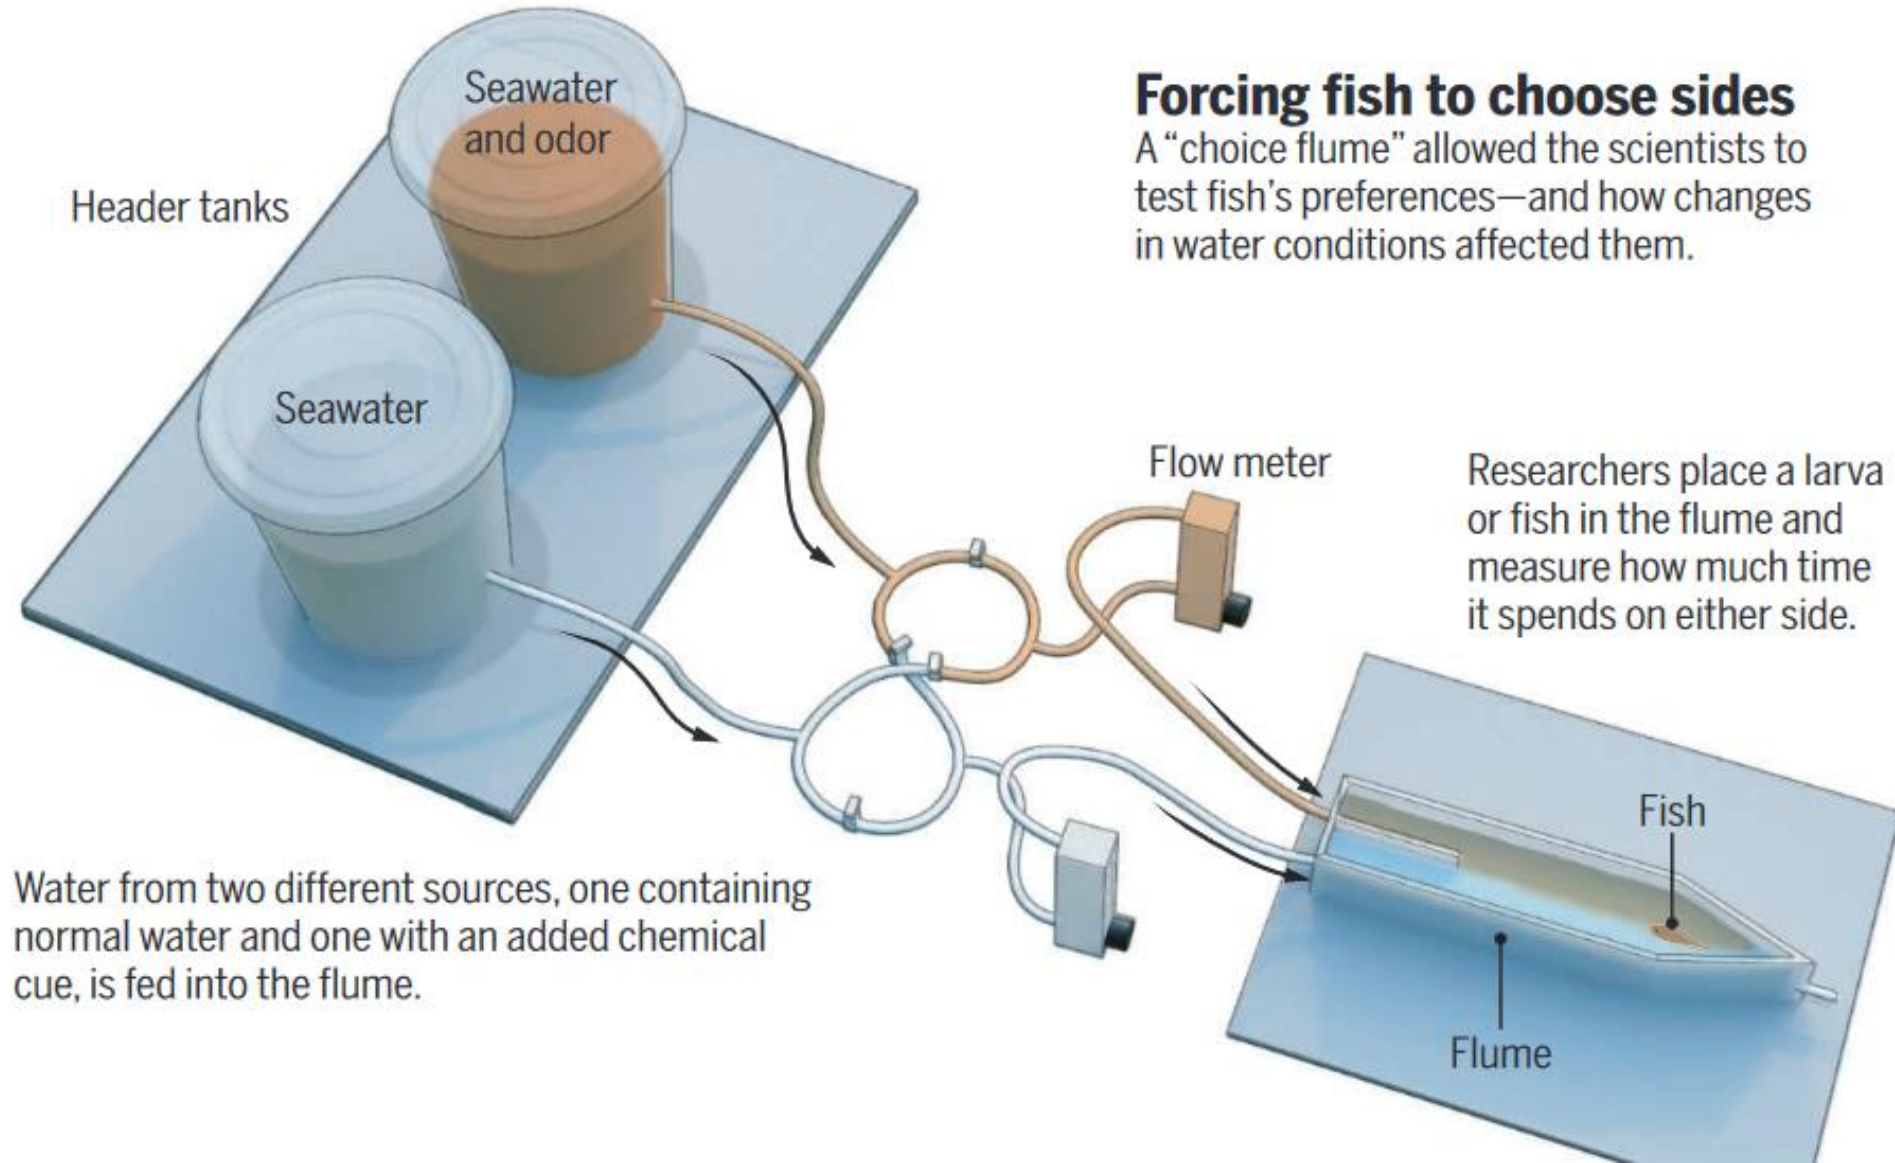

## Responses of coral larvae

Coral larvae discriminate among environments, as shown by their behavior in response to different waters (19), substrates (20), settlement-inducing crustose coralline algae (21), or biofilms (22). Additionally, some seaweeds chemically suppress the settlement and survival of coral larvae within centimeters of their thalli (15). The low survival of coral recruits at sites occupied by certain competitors (23) suggests that the avoidance of specific competitors by settling larvae could be adaptive. If so, chemically mediated larval behavior could affect recruitment densities and reef resilience.

To test this possibility, we exposed larvae of corals within the genus *Acropora* to cues from divergent environments. Acroporid corals are major providers of topographic complexity, which is negatively related to algal cover and positively related to fish density, biomass, diversity, and

Researchers place a larva or fish in the flume and measure how much time it spends on either side.

Water from two different sources, one containing normal water and one with an added chemical cue, is fed into the flume.

# SEA OF DOUBTS

Dozens of papers linking high carbon dioxide to unsettling changes in fish behavior fall under suspicion **By Martin Enserink**

**W**hen Philip Munday discussed his research on ocean acidification with more than 70 colleagues and students in a December 2020 Zoom meeting, he wasn't just giving a confident overview of

vision in 2012 and has since become a successful lab head at the University of Delaware (UD), Lewes.

In 2009, Munday and Dixon began to publish evidence that ocean acidification—a knock-on effect of the rising carbon dioxide (CO<sub>2</sub>) level in Earth's atmosphere—has

sets, led by fish physiologist Timothy Clark of Deakin University in Geelong, Australia, published a *Nature* paper reporting that in a massive, 3-year study, they didn't see these dramatic effects of acidification on fish behavior at all.

The paper has proved so polarizing in the

rication, they did say "methodological or analytical weaknesses" might have led to irreproducible results. And many in the research community knew the seven authors take a strong interest in sloppy science and fraud—they had blown the whistle on a 2016 *Science* paper by another former Ph.D.

Orange clownfish are among the tropical species studied in 22 papers now facing scrutiny.

asked three funders that together spent millions on Dixon's and Munday's work—the Australian Research Council (ARC), the U.S. National Science Foundation (NSF), and the U.S. National Institutes of Health (NIH)—to investigate possible fraud in 22 papers.

The request, which they shared with a *Science* reporter, rests on what they say is evidence of manipulation in publicly available raw data files for two papers, one published in *Science*, the other in *Nature Climate Change*, combined with remarkably large and "statistically impossible" effects from CO<sub>2</sub> reported in many of the other papers. They also provided testimony from former members of the Dixon and Munday labs, some of whom monitored Dixon's activities and concluded she made up data.

ARC and NSF declined to discuss the case with *Science*, but said they generally refer such cases to the research institutions—in this case JCU, the Georgia Institute of Technology, where Dixon worked between 2011 and 2015; and UD. NIH said it refers cases to the U.S. Office of Research Integrity, which does not comment on cases.

Munday calls the allegations of fraud "abhorrent" and "slandorous," and a JCU spokesperson says the university has dismissed the allegations after a preliminary investigation. (Munday retired from JCU in April and has moved to Tasmania, but emphasizes there is no connection between that timing and the allegations.) UD says it cannot comment on personnel matters; a Georgia Tech spokesperson declined to comment except to say the institute "takes all allegations of research misconduct seriously." Dixon denies making up data as well. "I fully stand by all the data I've collected, I stand by the papers that we've published," she told *Science* in a February interview. "The data was collected with integrity. I mean, I preach that to my students."

But multiple scientists and data experts unconnected to the Clark group who reviewed the case at *Science*'s request flagged a host of problems in the two data sets, and one of them found what he says are serious
